ABSTRACT:

PROBLEM TO BE SOLVED: To prevent redo of inventory determination operation by enabling checking of existence of articles failed to carry out inventory execution before inventory determination operation.

SOLUTION: An <u>inventory data processor</u> comprises: a single item master file in which a department is set corresponding to a single <u>item code of each article; an inventory</u> input data file which accumulates and stores the undetermined article inventory data; an inventory determination data file which accumulates and stores the inventory data of already determined articles. The counting of the number of single items of the articles belonging to the department is carried out for every department with reference to data of the single item master file. The counting of the number of single <u>items of already determined inventory</u> of the articles belonging to the department is carried out for every department with reference to data of inventory determination data file. The counting of the number of single items of already inputted article inventory data for the articles belonging to the department is carried out by department with reference to the data of an inventory input data file. The number of single <u>items of non-executed inventory</u> is computed for every department by subtracting the single <u>item number of executed inventory and the inventory input single item</u> number from the master single item number. The single item number of the non-executed inventory for every department is output.
